

AI FOR QA TESTERS

AI Regression Planning Template

Plan a risk-based regression set with AI as your brainstorming partner.

Introduction

Regression planning is about choosing what to re-test when something changes. AI can help you brainstorm impacted areas quickly — but you decide scope based on real risk and product knowledge.

Instructions

- Describe the change and the areas it touches.
- Ask AI to suggest potentially impacted areas and regression candidates.
- Filter the list by real risk, usage and history; cut the noise.
- Finalise a prioritised regression set you can justify.

Worked Example (planning prompt)

"We changed the checkout discount logic. List areas that could be impacted directly and indirectly, and suggest regression test scenarios grouped by risk (high/medium/low). Ask me for any context you need."

Blank Reusable Template

Area	Why impacted	Risk	Include?
		H / M / L	Yes / No
		H / M / L	Yes / No
		H / M / L	Yes / No

Prioritisation Guide

- Always include: critical paths, areas touched by the change, high-usage features.
- Usually include: features that share data/logic with the change.
- Time-permitting: low-risk, rarely-used areas.

Practical Exercise

For a recent change in any app you know, use the prompt to generate impacted areas, then build a one-page prioritised regression set and write one line justifying the scope.

Best Practices

- Anchor scope on risk, not on the size of the AI list.
- Always cover critical user journeys.
- Record why something was excluded — it protects you later.

Common Mistakes

- Running everything AI suggests with no prioritisation.
- Forgetting indirectly impacted areas.
- No record of scope decisions.

INSIDE STLC PRO TIP

AI widens your thinking on what could break; your job is to narrow it to what matters most. Smart regression is targeted, not exhaustive.
